APPLICANT(S) FOR DO/EO/US

Wolfgang KIESEWETTER, Bernd KNOFF, Manfred STEINER

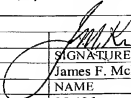

Applicant herewith submits to the United States Designated/Elected Office (DO/EO/US) the following items and other information:

1. ☒ This is a **FIRST** submission of items concerning a filing under 35 U.S.C. 371.
2. ☐ This is a **SECOND** or **SUBSEQUENT** submission of items concerning a filing under 35 U.S.C. 371
3. ☒ This express request to begin national examination procedures (35 U.S.C. 371(f)) at any time rather than delay Examination until the expiration of the applicable time limit set in 35 U.S.C. 371(b) and PCT Articles 22 and 39(1).
4. ☒ A proper Demand for International Preliminary Examination was made by the 19th month from the earliest claimed priority date.
5. ☒ A copy of the International Application as filed (35 U.S.C. 371(c)(2)).
 - a. ☐ is transmitted herewith (required only if not transmitted by the International Bureau).
 - b. ☒ has been transmitted by the International Bureau
 - c. ☐ is not required, as the application was filed in the United States Receiving Office (RO/US)
6. ☒ A translation of the International Application into English (35 U.S.C. 371(c)(2)).
7. ☒ Amendments to the claims of the International Application under PCT Article 19 (35 U.S.C. 371(c)(3))
 - a. ☐ are transmitted herewith (required only if not transmitted by the International Bureau).
 - b. ☐ have been transmitted by the International Bureau.
 - c. ☐ have not been made; however, the time limit for making such amendments has NOT expired.
 - d. ☒ have not been made and will not be made.
8. ☐ A translation of the amendments to the claims under PCT Article 19 (35 U.S.C. 371(c)(3)).
9. ☒ An oath or declaration of the inventor(s) (35 U.S.C. 371(c)(4)) (unexecuted)
10. ☒ A translation of the annexes to the International Preliminary Examination Report under PCT Article 36 (35 U.S.C. 371(c)(5)).

Item 11. to 16. below concern other document(s) or information included:

11. ☐ An Information Disclosure Statement under 37 CFR 1.97 and 1.98.
12. ☐ An assignment document for recording. A separate cover sheet in compliance with 37 CFR 3.28 and 3.31 is included.
13. ☒ A **FIRST** preliminary amendment.
☐ A **SECOND** or **SUBSEQUENT** preliminary amendment
14. ☒ A substitute specification and marked-up copy thereof.
15. ☐ A change of power of attorney and/or address letter.
16. ☒ Other items or information:

Title: BRAKE SYSTEM FOR A VEHICLE

PRELIMINARY AMENDMENT

Commissioner for Patents
Washington, D.C. 20231

Sir:

Please enter the following amendments to the specification, claims and abstract prior to the examination of the application.

IN THE SPECIFICATION:

A substitute specification and a marked-up copy thereof is submitted herewith.

IN THE CLAIMS:

Please cancel claims 1-19.

Please add the following new claims 20-32:

20. (New) Brake system with two brake circuits for a vehicle, comprising a brake servo assistance unit for automatic generation of brake force, and at least one pressure sensor for generation of a measuring signal representative of an activity on a driver's part and fed to a brake pressure

control unit, with an activation control signal for actuation of the brake servo assistance unit being generated in the event measuring signals from the sensors exceed a reference value, wherein

two pressure sensors are provided and have different reference values assigned thereto, each of the pressure sensors being operatively associated with one of the brake circuits (11a; 11b), and the activation control signal is generated for temporary activation of the brake servo assistance unit for a limited time period in the event that a higher of the reference value from the first pressure sensor is exceeded and a lower of the reference values for the second pressure sensor has not yet been attained.

21. (New) Brake system according to claim 20, wherein at least one of absolute values and gradients are generated as the measuring signals.

22. (New) Brake system according to claim 20, wherein one of the reference values is generated by multiplying the first reference value by a reduction factor of less than one.

23. (New) Brake system according to claim 20, wherein the temporary activation is maintained for a limited, defined number of working cycles of the control unit and thereafter a deactivation control signal is generated for deactivation of the brake servo assistance unit.

24. (New) Brake system according to claim 20, wherein the temporary activation is maintained in the event that the measuring signal from a second of

the pressure sensors exceeds a reduced reference value during a defined number of working cycles.

25. (New) Brake system according to claim 20, wherein a deactivation control signal deactivating the brake servo assistance unit is generated in the event that the measuring signal from one of the sensors falls below a reference value.

26. (New) Brake system according to claim 20, wherein at least one travel sensor is provided for measuring the activity on the driver's part.

27. (New) Brake system according to claim 26, wherein an activation control signal is generated in the event that a pressure gradient of one pressure sensor and a speed value calculated from successive measuring signals of the travel sensor each exceed a reference value.

28. (New) Brake system according to claim 26, wherein an activation control signal is generated in the event that a pressure value of the pressure sensor and a speed value of the travel sensor each exceed a reference value.

29. (New) Brake system according to claim 26, wherein an activation control signal is generated in the event that a pressure gradient of the pressure sensor and a travel of the travel sensor each exceed a reference value.

30. (New) Brake system according to claims 26, wherein a deactivation control signal is generated in the event that the measuring signal from the travel sensor falls below a reference value.

31. (New) Brake system according to claim 20, wherein a trip switch is provided for deactivation of the brake servo assistance unit operatively installed in the brake booster of the brake system, whereby a deactivation control signal is in the event that a measuring signal of the trip switch falls below a reference value.

32. (New) Brake system according to claim 20, wherein the measuring signals from the sensors for generating the activation control signal are such as to occur within a defined time window.

IN THE ABSTRACT:

Please make the following changes to the abstract :

(A copy of the marked-up version of the abstract is attached to this Amendment.)

A brake system for a vehicle is equipped with a brake servo assistance unit for the automatic generation of brake force and with at least one sensor for the generation of a measuring signal. This signal represents an activity on the part of the driver and can be fed to a brake pressure control unit. An activation control signal for the actuation of the brake servo assistance unit can be generated should the measuring signal lie within an activation value range. In order to improve operating reliability, at least two sensors are provided for measurement of an activity on the part of the driver, and an activation control signal can be generated should the measuring signals from the sensors each exceed a reference value.

REMARKS

Entry of the amendments to the specification, claims and abstract before examination of the application is respectfully requested.

If there are any questions regarding this amendment or the application in general, a telephone call to the undersigned would be appreciated since this should expedite the prosecution of the application for all concerned.

If necessary to effect a timely response, this paper should be considered as a petition for an Extension of Time sufficient to effect a timely response, and please charge any deficiency in fees or credit any overpayments to Deposit Account No. 05-1323 (Docket #225/50783).

December 31, 2001

Respectfully submitted,

In order to improve [the] operating reliability, at least two sensors are provided for [the] measurement of an activity on the part of the driver, and an activation control signal can be generated should the measuring signals from the sensors each exceed a reference value.

Attorney Docket No. 225/50783
Substitute Specification

BRAKE SYSTEM FOR A VEHICLE

BACKGROUND OF THE INVENTION

The present invention relates to a brake system for a vehicle.

DE 43 29 140 A1 discloses a brake system with two brake circuits in which a brake servo assistance unit performs an automatic braking action. The brake servo assistance unit is activated when the brake pedal is operated very rapidly. For this purpose the brake system has a pedal position sensor and a pressure sensor.

DE 195 20 609 A1 describes a pressure sensor for measuring the pressure arranged at the outlet of the brake master cylinder in both brake circuits of the brake system.

EP 08 19 591 A1 discloses a method for performing an automatic braking action. The brake servo assistance unit is first activated when the accelerator pedal return rate of travel exceeds a certain threshold value, and this temporary activation is maintained only if a brake pedal actuation occurs during a specific time window.

SUMMARY OF THE INVENTION

An object of the present invention is to avoid unnecessary activations of the brake servo assistance unit and at the same time to ensure a fail-safe operation of the brake system.

According to the invention this object has been achieved by providing that two pressure sensors are provided and have different reference values assigned thereto, each of the pressure sensors being operatively associated with one of the brake circuits, and the activation control signal is generated for temporary activation of the brake servo assistance unit for a limited time period, in the event that a higher of the reference values from the first pressure sensor is exceeded and a lower of the reference values for the second pressure sensor has not yet been attained.

According to the invention a temporary, preventative activation is performed for a limited period of time should the higher reference value of one sensor be exceeded, while the lower reference value of the second sensor has not yet been attained. In this situation the conditions for unrestricted activation are not yet met, but activation is nonetheless undertaken for the limited period of time and is advantageously maintained provided that the reduced reference value of the second sensor is exceeded during the period of activation. If the conditions for permanent activation are not fulfilled during the defined period, a deactivation control signal is automatically generated.

This improved procedure affords the advantage that additional brake force is made available within a shorter response time. Furthermore, the reactive effect on the driver is reduced, since owing to the limited period of time the braking action only takes partial effect. This avoids irritation being caused to the driver.

The activation control signal is suitably generated should a gradient be calculated from successive measuring signals of each of the two sensors and the gradients for each of the two sensors exceed a reference value. As an alternative activation criterion, however, it is also contemplated to take account of the gradient for one sensor and the absolute value for the second sensor. It is furthermore contemplated to utilize the absolute values from both sensors in order to assess whether activation is to be undertaken.

For deactivation of the brake servo assistance unit it is duly sufficient for the measuring signal from just one sensor to fall below a reference value. Adopting this approach ensures that even in the event of one sensor failing, the automatic generation of brake force is deactivated again provided that the measuring signal from at least one intact sensor delivers a measuring signal that lies within the deactivation value range. This makes it possible to avoid operating situations in which the brake system erroneously delivers brake force even though a situation that justifies the provision of additional brake force no longer exists; that is the brake system is of redundant design with regard to deactivation and operating safety is improved.

The values for the activation range and the deactivation range may differ, for example, activation occurring at higher values, or in the event of higher gradients derived from the absolute measuring signals, than deactivation. The differing activation and deactivation conditions increase the margin of safety against erroneous, accidental activation of the brake system.

It may be appropriate to configure at least one sensor as a travel sensor. Where one pressure sensor and one travel sensor are provided, a current speed value is preferably determined from successive measuring signals of the travel sensor, and together with the pressure gradient of the pressure sensor this is used as the basis for the query as to whether the brake system is to be activated. As an alternative condition, however, account may also be taken of the pressure/speed or pressure gradient/travel combination.

In an advantageous development, it is merely sufficient for the measuring signal of the travel sensor to fall below a reference value, in order to trigger the deactivation control signal.

It may be advisable to provide alternative conditions both for the activation and for the deactivation of the brake system. Activation or deactivation then occurs if just one of the formulated conditions is met.

BRIEF DESCRIPTION OF THE DRAWINGS

Other objects, advantages and novel features of the present invention will become apparent from the following detailed description of the invention when considered in conjunction with the accompanying drawings.

The sole figure is a schematic circuit diagram of the hydraulic brake system according to the present invention.

DETAILED DESCRIPTION OF THE DRAWINGS

The brake system 1 of a motor vehicle comprises an actuating unit 2 for activation of the wheel brake by the driver, a hydraulic unit 3 for transmission

and modulation of the required brake pressure and wheel brake units 4 on the front left (FL), front right (FR), rear left (RL) and rear right (RR) wheels of the vehicle. The actuating unit 2 comprises a brake pedal 5, a booster 6, a master cylinder 7 and a reservoir tank 8[; in]. In addition, a trip switch 9 and a travel sensor 10 are assigned to the actuating unit 2. The hydraulic unit 3 comprises two brake circuits 11a, 11b, which are of inverse design construction. The first brake circuit 11a supplies brake pressure to the RL and FR wheel brake units, the second brake circuit 11b is assigned to FL and RR wheel brake units.

A brake light switch may also be used in place of the trip switch 9.

When the brake pedal 5 is actuated, the pedal force applied by the driver is boosted by the booster 6, the force generated by the booster 6 being converted in the master cylinder 7, which is fed with hydraulic medium from the reservoir tank 8, into hydraulic brake pressure, which is delivered to the two brake circuits 11a, 11b of the hydraulic unit 3.

The following description of the hydraulic unit 3 relates only to the first brake circuit 11a, the second brake circuit 11b in the illustrated embodiment shown being of similar construction to the first brake circuit 11a. All components of the hydraulic unit 3 can be adjusted by signals from a control unit (not shown).

The brake pressure generated in the master cylinder 7 is delivered by way of a hydraulic line 12 to the RL and FR wheel brake units of the first brake circuit 11a. The hydraulic line 12 comprises three sections 12a, b, c, the first section 12a branching off from the master cylinder 7 dividing into the two

further sections 12b, c, which are each assigned to a wheel brake unit, FR and RL respectively. A servo valve 13a, b, c is arranged in each section 12a, b, c of the hydraulic line 12 and a non-return valve is assigned to each servo valve 13a, b, c. The non-return valve assigned to the first servo valve 13a in the common line section 12a opens in the direction of the wheel brake units, whereas the non-return valves assigned to the other servo valves 13b, c open in the direction of the actuating unit 2. The common line section 12a is connected to a compensating accumulator 21 upstream of the servo valve 13a.

When the driver operates the brake pedal 2, thereby generating a brake pressure, control signals from the control unit move the servo valves 13a, b, c into the opening position, so that the brake pressure from the actuating unit 2 can be delivered to the wheel brake units 4 in order to generate a wheel brake force.

The return flow of hydraulic medium is by way of a return line 14, which comprises two line sections 14b, c, which branch off from the feed line sections 12b, c, and a common line section 14a, into which the sections 14b, c open and which in turn opens into the upper section 12a of the hydraulic line 12. Each servo valve 15a, b, c is arranged in each respective section 14a, b, c of the return line 14. An intermediate accumulator and a non-return valve opening in the direction of the return flow are situated in the upper line section 14a between the union of the lower line sections 14b, c and the upper servo valve 15a. The servo valves 15a, b, c may be opened by the control unit for the return flow of hydraulic medium.

In the brake circuit 11a of the hydraulic unit 3 an automatic brake servo assistance unit 16 is furthermore provided. The unit 16 comprises a hydraulic pump 17, a hydraulic motor 18 and an intermediate accumulator 19 in a line 20 which branches off from the section 14a of the return line 14 and which opens into the common line section 12a of the hydraulic line 12 downstream of the servo valve 13a. On actuation of the hydraulic motor 18 and the hydraulic pump 17 respectively, additional brake pressure is generated, which additional pressure is fed into the common line section 12a and delivered to the wheel brake units 4, thereby generating a boosted brake force. The actuation of hydraulic motor 18 and hydraulic pump 17, both the activation and the deactivation, is triggered by control signals from the control unit as a function of input signals which are generated as measuring signals by the sensors 9, 10 in the actuating unit 2 and, where applicable, by other sensors 22, 23 in the hydraulic unit 3.

The sensor 9 in the actuating unit 2 is configured as a trip switch which is installed in the booster 6 and has the function of deactivating the automatic brake servo assistance unit 16 as soon as the brake pedal 5, starting from an actuation position, covers a release travel towards the initial home position. In this event, the driver withdraws the pedal force, from which it can be inferred that no additional brake servo assistance is required, whereupon the servo assistance unit is deactivated.

The further sensor 10 in the actuating unit 2 is configured as a travel sensor, which senses either the control movement of the brake pedal or the control movement of the cylinder in the master cylinder 7 corresponding to the

control movement of the brake pedal. The sensor 22 in the hydraulic unit 3 is a pressure sensor which is arranged in the common line section 12a and measures the pressure in the hydraulic line 12.

The brake servo assistance unit 16 is activated in the event of at least one of the following criteria being fulfilled:

- The pressure gradient in the hydraulic line 12 is calculated from successive measuring signals of the pressure sensor 22 in the control unit. The speed with which the brake pedal 5 or the cylinder of the master cylinder 7 is moved is correspondingly calculated from successive measuring signals of the travel sensor 10. Should both the pressure gradient and the speed exceed a reference value assigned to each of them respectively, an activation control signal is generated for activation of the brake servo assistance unit 16.

- The pressure value determined in the pressure sensor 22 and the speed value derived from the measuring signals of the travel sensor 10 exceed a reference value assigned to each of them respectively.

- The pressure gradient derived from the measuring signals of the pressure sensor 22 and the travel determined in the travel sensor exceed a reference value assigned to each of them respectively.

- The measuring signals from the pressure sensor 22 and the measuring signals from the pressure sensor 23 exceed a reference value in each case. Pressure values and/or pressure gradients may be used as measuring signals. Instead of an arrangement of the pressure sensors spread over two

brake circuits, it may also be appropriate to arrange both pressure sensors in one brake circuit.

The measuring signals from the sensors must in each case exceed an assigned reference value for an activation control signal to be generated. The reference values may assume different values, especially where two sensors of the same type are provided, with the lower value being obtained through multiplying the higher value by a reduction factor, which suitably lies between 0.5 and 1.

In this case, a two-stage activation is performed. Once the higher reference value of a sensor is exceeded, but the lower reference value of the second sensor has not yet been attained, a temporary activation can occur for a limited period, which is cancelled again, provided that the lower reference value of the second sensor is not exceeded during the set period of time. The period of time according to which the temporary activation is proportionately calculated is advantageously between one and ten working cycles of the brake system.

Should a higher reference value and at least one lower reference value be exceeded simultaneously in both sensors, activation occurs with no time limit. In this case, deactivation occurs only when the deactivation conditions are fulfilled.

The brake servo assistance unit 16 is deactivated by way of the trip switch 9 if the forces fall below a force reference value. The trip switch switches as a function of the pedal force acting on the brake pedal.

Deactivation may also occur if the measuring signal from the travel sensor 10 falls below a reference value, which may differ from the corresponding reference value for activation and may in particular assume a higher absolute value, in order to achieve a relatively rapid deactivation of the servo assistance unit. In addition, further deactivation criteria may be formulated, which are dependent on the pressure value, the pressure gradient or on the speed of the brake pedal control movement. If the deactivation criteria are formulated as a function of the sensor values of the travel sensor 10 or the pressure sensor 22, the trip switch 9 may also be dispensed with.

Taking account of two different measuring principles by using a pressure sensor and a travel sensor has the advantage that the failure probability of the brake servo assistance unit 16 is reduced, because the different types of sensors react to a fault in different ways.

In the second brake circuit 11b, a further pressure sensor 23 measures the pressure in the second hydraulic line supplying the brake circuit 11b. Doubling the number of pressure sensors in different brake circuits allows the brake system to be designed with redundancy and also formulated with limiting conditions.

The brake servo assistance unit is activated, for example, when the pressure gradients of both pressure sensors 22, 23 exceed a reference value, the reference values being different. In an alternative embodiment, activation occurs if the gradient of one pressure sensor and the pressure value of the second pressure sensor each exceed a reference value. In both cases it is possible to set a

time window, during which the measuring signals must meet the specified conditions.

Deactivation advantageously occurs should one of the two pressure signals fall below a further reference value, mainly the deactivation threshold.

The two pressure sensors are appropriately arranged in different brake circuits.

In preferred embodiments, just two pressure sensors are used throughout the entire brake system. A force sensor or force sensors may also be used instead of the pressure sensor or pressure sensors.

Use of the present invention is feasible both in open hydraulic circuits and in closed hydraulic circuits of the brake system. The brake system according to the invention may be designed both with diagonally split brake circuits and with front axle/rear axle split brake circuits.

Abstract

A brake system for a vehicle is equipped with a brake servo assistance unit for the automatic generation of brake force and with at least one sensor for the generation of a measuring signal. This signal represents an activity on the part of the driver and can be fed to a brake pressure control unit. An activation control signal for the actuation of the brake servo assistance unit can be generated should the measuring signal lie within an activation value range. In order to improve operating reliability, at least two sensors are provided for measurement of an activity on the part of the driver, and an activation control signal can be generated should the measuring signals from the sensors each exceed a reference value.

BRAKE SYSTEM FOR A VEHICLE

BACKGROUND OF THE INVENTION

The present invention relates to a brake system for a vehicle [according to the precharacterizing clause of Claim 1].

[The publication DE 44 27 246 A1 discloses a brake system for a motor vehicle for automatically initiating a braking action with an enhanced brake pressure in excess of driver demand in the event of an emergency braking movement made by the driver's foot. The pressure applied by the driver by way of the brake pedal is registered by a pressure sensor; if the pressure exceeds a threshold value, an activation control signal is generated for initiation of the braking action with enhanced brake pressure.

According to a design disclosed by DE 196 41 470 A1, a travel sensor, which monitors the range of movement of the driver's foot, is arranged in the footwell of the vehicle. The travel sensor, however, only measures the initiation of a movement, not the speed of the movement. A second travel sensor on the brake pedal determines the time difference between the generation of the measuring signals of both sensors and forms the basis for deciding whether this constitutes an emergency braking movement.

In the case of the designs described there is the problem that, should a sensor fail, there is no possibility of detecting an emergency reaction on the part of the driver, and it is no longer possible to activate the automatic brake device.

Furthermore, in the event of a fault it is not possible to deactivate an already activated brake device, because as the criterion for deactivation the measuring signals of the sensors must fall below reference values, but with defective sensors such measuring signals cannot be generated correctly, if at all.] DE 43 29 140 A1 discloses a brake system with two brake circuits in which a brake servo assistance unit performs an automatic braking action. The brake servo assistance unit is activated when the brake pedal is operated very rapidly. For this purpose the brake system has a pedal position sensor and a pressure sensor.

DE 195 20 609 A1 describes a pressure sensor for measuring the pressure arranged at the outlet of the brake master cylinder in both brake circuits of the brake system.

EP 08 19 591 A1 discloses a method for performing an automatic braking action. The brake servo assistance unit is first activated when the accelerator pedal return rate of travel exceeds a certain threshold value, and this temporary activation is maintained only if a brake pedal actuation occurs during a specific time window.

SUMMARY OF THE INVENTION

[The problem addressed by the invention is to improve the operating reliability of an automatic brake system.

According to the invention this problem is solved by the features of Claim

1.

According to the innovation at least two sensors are provided, the measuring signals from each of the sensors needing to lie within defined activation value ranges for actuation of the brake servo assistance unit to occur; otherwise automatic activation of the brake servo assistance unit is not permitted. This permits a more precise definition of situations in which automatic braking is to be initiated. The system is designed with redundancy, because the activation conditions can be defined in such a way that the signals of one sensor for the activation of the brake system lie in a higher value range, whereas the signals of the second sensor lie in a lower value range.

In a preferred embodiment a temporary, preventative activation can be performed for a limited period of time should the higher reference value of one sensor be exceeded, whilst the lower reference value of the second sensor has not yet been attained. In this situation the conditions for unrestricted activation are not yet met, but activation is nonetheless undertaken for the limited period of time and is advantageously maintained provided that the reduced reference value of the second sensor is exceeded during the period of activation. If the conditions for permanent activation are not fulfilled during the defined period, a deactivation control signal is automatically generated] an object of the present invention is to avoid unnecessary activations of the brake servo assistance unit and at the same time to ensure a fail-safe operation of the brake system.

According to the invention this object has been achieved by providing that two pressure sensors are provided and have different reference values assigned

thereto, each of the pressure sensors being operatively associated with one of the brake circuits, and the activation control signal is generated for temporary activation of the brake servo assistance unit for a limited time period, in the event that a higher of the reference values from the first pressure sensor is exceeded and a lower of the reference values for the second pressure sensor has not yet been attained.

According to the invention a temporary, preventative activation is performed for a limited period of time should the higher reference value of one sensor be exceeded, while the lower reference value of the second sensor has not yet been attained. In this situation the conditions for unrestricted activation are not yet met, but activation is nonetheless undertaken for the limited period of time and is advantageously maintained provided that the reduced reference value of the second sensor is exceeded during the period of activation. If the conditions for permanent activation are not fulfilled during the defined period, a deactivation control signal is automatically generated.

This improved procedure affords the advantage that additional brake force is made available within a shorter response time. Furthermore, the reactive effect on the driver is reduced, since owing to the limited period of time the braking action only takes partial effect. This avoids [causing] irritation being caused to the driver.

The activation control signal is suitably generated should a gradient be calculated from successive measuring signals of each of the two sensors and the

gradients for each of the two sensors exceed a reference value. As an alternative activation criterion, however, it is also [possible] contemplated to take account of the gradient for one sensor and the absolute value for the second sensor. It is furthermore [possible] contemplated to utilize the absolute values from both sensors in order to assess whether activation is to be undertaken.

For deactivation of the brake servo assistance unit it is duly sufficient for the measuring signal from just one sensor to fall below a reference value. Adopting this approach ensures that even in the event of one sensor failing, the automatic generation of brake force is deactivated again provided that the measuring signal from at least one intact sensor delivers a measuring signal that lies within the deactivation value range. This makes it possible to avoid operating situations in which the brake system erroneously delivers brake force even though a situation that justifies the provision of additional brake force no longer exists; that is the brake system is of redundant design with regard to deactivation and operating safety is improved.

The values for the activation range and the deactivation range may differ, for example, activation occurring at higher values, or in the event of higher gradients derived from the absolute measuring signals, than deactivation. The differing activation and deactivation conditions increase the margin of safety against erroneous, accidental activation of the brake system.

[In a first advantageous embodiment, two pressure sensors are provided. The use of two sensors of the same type permits an activation of the brake servo

assistance unit for differing pressure values or pressure gradients of the pressure sensors, thereby increasing the fail-safety.]

It may be appropriate[, however,] to [design] configure at least one sensor as a travel sensor. Where one pressure sensor and one travel sensor are provided, a current speed value is preferably determined from successive measuring signals of the travel sensor, and together with the pressure gradient of the pressure sensor this is used as the basis for the query as to whether the brake system is to be activated. As an alternative condition, however, account may also be taken of the pressure/speed or pressure gradient/travel combination.

In an advantageous development, it is merely sufficient for the measuring signal of the travel sensor to fall below a reference value, in order to trigger the deactivation control signal.

It may be advisable to provide alternative conditions both for the activation and for the deactivation of the brake system. Activation or deactivation then occurs if just one of the formulated conditions is met.

BRIEF DESCRIPTION OF THE DRAWINGS

[Further advantages and suitable embodiments are set out in the further claims, the description of the figures and the drawing, which represents a circuit diagram of a hydraulic brake system according to the invention.] Other objects, advantages and novel features of the present invention will become apparent

from the following detailed description of the invention when considered in conjunction with the accompanying drawings.

The sole figure is a schematic circuit diagram of the hydraulic brake system according to the present invention.

DETAILED DESCRIPTION OF THE DRAWINGS

The brake system 1 of a motor vehicle comprises an actuating unit 2 for activation of the wheel brake by the driver, a hydraulic unit 3 for transmission and modulation of the required brake pressure and wheel brake units 4 on the front left (FL), front right (FR), rear left (RL) and rear right (RR) wheels of the vehicle. The actuating unit 2 comprises a brake pedal 5, a booster 6, a master cylinder 7 and a reservoir tank 8; in addition, a trip switch 9 and a travel sensor 10 are assigned to the actuating unit 2. The hydraulic unit 3 comprises two brake circuits 11a, 11b, which are of inverse design construction. The first brake circuit 11a supplies brake pressure to the RL and FR wheel brake units, the second brake circuit 11b is assigned to FL and RR wheel brake units.

A brake light switch may also be used in place of the trip switch 9.

When the brake pedal 5 is actuated, the pedal force applied by the driver is boosted by the booster 6, the force generated by the booster 6 being converted in the master cylinder 7, which is fed with hydraulic medium from the reservoir tank 8, into hydraulic brake pressure, which is delivered to the two brake circuits 11a, 11b of the hydraulic unit 3.

The following description of the hydraulic unit 3 relates only to the first brake circuit 11a, the second brake circuit 11b in the [exemplary] illustrated embodiment shown being of similar construction to the first brake circuit 11a. All components of the hydraulic unit 3 can be adjusted by [means of] signals from a control unit (not shown).

The brake pressure generated in the master cylinder 7 is delivered by way of a hydraulic line 12 to the RL and FR wheel brake units of the first brake circuit 11a. The hydraulic line 12 comprises three sections 12a, b, c, [a] the first section 12a branching off from the master cylinder 7 dividing into the two further sections 12b, c, which are each assigned to a wheel brake unit, FR and RL respectively. A servo valve 13a, b, c is arranged in each section 12a, b, c of the hydraulic line 12 and a non-return valve is assigned to each servo valve 13a, b, c[, the]. The non-return valve assigned to the first servo valve 13a in the common line section 12a [opening] opens in the direction of the wheel brake units, whereas the non-return valves assigned to the other servo valves 13b, c open in the direction of the actuating unit 2. The common line section 12a is connected to a compensating accumulator 21 upstream of the servo valve 13a.

When the driver operates the brake pedal 2, thereby generating a brake pressure, control signals from the control unit move the servo valves 13a, b, c into the opening position, so that the brake pressure from the actuating unit 2 can be delivered to the wheel brake units 4 in order to generate a wheel brake force.

The return flow of hydraulic medium is by way of a return line 14, which comprises two line sections 14b, c, which branch off from the feed line sections 12b, c, and a common line section 14a, into which the sections 14b, c open and which in turn opens into the upper section 12a of the hydraulic line 12. [A] Each servo valve 15a, b, c is arranged in each respective section 14a, b, c of the return line 14[, an]. An intermediate accumulator and a non-return valve opening in the direction of the return flow [being] are situated in the upper line section 14a between the union of the lower line sections 14b, c and the upper servo valve 15a. The servo valves 15a, b, c may be opened by the control unit for the return flow of hydraulic medium.

In the brake circuit 11a of the hydraulic unit 3 an automatic brake servo assistance unit 16 is furthermore provided[, which]. The unit 16 comprises a hydraulic pump 17, a hydraulic motor 18 and an intermediate accumulator 19 in a line 20[,] which branches off from the section 14a of the return line 14 and which opens into the common line section 12a of the hydraulic line 12 downstream of the servo valve 13a. On actuation of the hydraulic motor 18 and the hydraulic pump 17 respectively, additional brake pressure is generated, which additional pressure is fed into the common line section 12a and delivered to the wheel brake units 4, thereby generating a boosted brake force. The actuation of hydraulic motor 18 and hydraulic pump 17 [-], both the activation and the deactivation, is triggered by control signals from the control unit as a function of input signals[,] which are generated as measuring signals by the

sensors 9, 10 in the actuating unit 2 and, where applicable, by other sensors 22, 23 in the hydraulic unit 3.

The sensor 9 in the actuating unit 2 is [designed] configured as a trip switch[,] which is installed in the booster 6 and has the function of deactivating the automatic brake servo assistance unit 16 as soon as the brake pedal 5, starting from an actuation position, covers a release travel towards the initial home position. In this event, the driver withdraws the pedal force, from which it can be inferred that no additional brake servo assistance is required, whereupon the servo assistance unit is deactivated.

The further sensor 10 in the actuating unit 2 is [designed] configured as a travel sensor, which senses either the control movement of the brake pedal or the control movement of the cylinder in the master cylinder 7 corresponding to the control movement of the brake pedal. The sensor 22 in the hydraulic unit 3 is [designed as] a pressure sensor[,] which is arranged in the common line section 12a and measures the pressure in the hydraulic line 12.

The brake servo assistance unit 16 is activated in the event of at least one of the following criteria being fulfilled:

- The pressure gradient in the hydraulic line 12 is calculated from successive measuring signals of the pressure sensor 22 in the control unit. The speed with which the brake pedal 5 or the cylinder of the master cylinder 7 is moved is correspondingly calculated from successive measuring signals of the travel sensor 10. Should both the pressure gradient and the speed exceed a

Attorney Docket No. 225/50783
Marked-up Specification

reference value assigned to each of them respectively, an activation control signal is generated for activation of the brake servo assistance unit 16.

- The pressure value determined in the pressure sensor 22 and the speed value derived from the measuring signals of the travel sensor 10 exceed a reference value assigned to each of them respectively.

- The pressure gradient derived from the measuring signals of the pressure sensor 22 and the travel determined in the travel sensor exceed a reference value assigned to each of them respectively.

- The measuring signals from the pressure sensor 22 and the measuring signals from the pressure sensor 23 exceed a reference value in each case. Pressure values and/or pressure gradients may be used as measuring signals. Instead of an arrangement of the pressure sensors spread over two brake circuits, it may also be appropriate to arrange both pressure sensors in one brake circuit.

The measuring signals from the sensors must in each case exceed an assigned reference value for an activation control signal to be generated. The reference values may assume different values, especially where two sensors of the same type are provided, with the lower value being obtained through multiplying the higher value by a reduction factor, which suitably lies between 0.5 and 1.

[If need be] In this case, a two-stage activation is performed. Once the higher reference value of a sensor is exceeded, but the lower reference value of the second sensor has not yet been attained, a temporary activation can occur for a limited period, which is cancelled again, provided that the lower reference value of the second sensor is not exceeded during the set period of time. The period of time according to which the temporary activation is proportionately calculated is advantageously between one and ten working cycles of the brake system.

Should a higher reference value and at least one lower reference value be exceeded simultaneously in both sensors, activation occurs with no time limit. In this case, deactivation occurs only when the deactivation conditions are fulfilled.

[Where appropriate, a time window is allowed, within which the measuring signals or the values derived from the measuring signals from travel sensor 10 and pressure sensor 22 must exceed the corresponding reference value.]

The brake servo assistance unit 16 is deactivated by way of the trip switch 9 [should] if the forces fall below a force reference value. The trip switch switches as a function of the pedal force acting on the brake pedal.

[It may also be expedient, however, to initiate the deactivation should the measuring signal from the travel sensor 10 fall below a reference value, which

may differ from the corresponding reference value for activation and may in particular assume a higher absolute value, in order to achieve a relatively rapid deactivation of the servo assistance unit] Deactivation may also occur if the measuring signal from the travel sensor 10 falls below a reference value, which may differ from the corresponding reference value for activation and may in particular assume a higher absolute value, in order to achieve a relatively rapid deactivation of the servo assistance unit. In addition, further deactivation criteria may be formulated, which are dependent on the pressure value, the pressure gradient or on the speed of the brake pedal control movement. If the deactivation criteria are formulated as a function of the sensor values of the travel sensor 10 or the pressure sensor 22, the trip switch 9 may also be dispensed with.

Taking account of two different measuring principles by using a pressure sensor and a travel sensor has the advantage that the failure probability of the brake servo assistance unit 16 is reduced, because the different types of sensors react to a fault in different ways.

In the second brake circuit 11b, a further pressure sensor 23 measures the pressure in the second hydraulic line supplying the brake circuit 11b. Doubling the number of pressure sensors in different brake circuits allows the brake system to be designed with redundancy and also formulated with limiting conditions.

[Consideration is given to activation of the brake servo assistance unit in particular where the pressure gradients of both pressure sensors 22, 23 exceed a reference value, it being possible to set the reference values at different levels. In an alternative embodiment, activation occurs if the gradient of one pressure sensor and the pressure value of the second pressure sensor each exceed a reference value. In both cases it is possible to set a time window, during which the measuring signals must meet the specified conditions] The brake servo assistance unit is activated, for example, when the pressure gradients of both pressure sensors 22, 23 exceed a reference value, the reference values being different. In an alternative embodiment, activation occurs if the gradient of one pressure sensor and the pressure value of the second pressure sensor each exceed a reference value. In both cases it is possible to set a time window, during which the measuring signals must meet the specified conditions.

Deactivation advantageously occurs should one of the two pressure signals fall below a further reference value, mainly the deactivation threshold.

The two pressure sensors are appropriately arranged in different brake circuits. [It may also be appropriate, where necessary, however, to provide two sensors in one brake circuit.]

In preferred embodiments, just two pressure sensors[, or just one pressure sensor and one travel sensor, or just one pressure sensor, one travel sensor and one trip switch] are used throughout the entire brake system. A force sensor or

Attorney Docket No. 225/50783
Marked-up Specification

force sensors may also be used [as equivalents to] instead of the pressure sensor or pressure sensors.

Use of the present invention is feasible both in open hydraulic circuits and in closed hydraulic circuits of the brake system. The brake system according to the invention may be designed both with diagonally split brake circuits and with front axle/rear axle split brake circuits.

Abstract

A brake system for a vehicle is equipped with a brake servo assistance unit for the automatic generation of brake force and with at least one sensor for the generation of a measuring signal[, which]. This signal represents an activity on the part of the driver and can be fed to a brake pressure control unit[, it being possible to generate an]. An activation control signal for the actuation of the brake servo assistance unit can be generated should the measuring signal lie within an activation value range. In order to improve [the] operating reliability, at least two sensors are provided for [the] measurement of an activity on the part of the driver, and an activation control signal can be generated should the measuring signals from the sensors each exceed a reference value.

i/p.b.

Brake system for a vehicle

The invention relates to a brake system for a vehicle
5 according to the precharacterizing clause of Claim 1.

The publication DE 44 27 246 A1 discloses a brake system
for a motor vehicle for automatically initiating a
braking action with an enhanced brake pressure in excess
10 of driver demand in the event of an emergency braking
movement made by the driver's foot. The pressure applied
by the driver by way of the brake pedal is registered by
a pressure sensor; if the pressure exceeds a threshold
value, an activation control signal is generated for
15 initiation of the braking action with enhanced brake
pressure.

According to a design disclosed by DE 196 41 470 A1, a
travel sensor, which monitors the range of movement of
20 the driver's foot, is arranged in the footwell of the
vehicle. The travel sensor, however, only measures the
initiation of a movement, not the speed of the movement.
A second travel sensor on the brake pedal determines the
time difference between the generation of the measuring
25 signals of both sensors and forms the basis for deciding
whether this constitutes an emergency braking movement.

In the case of the designs described there is the problem
that, should a sensor fail, there is no possibility of
30 detecting an emergency reaction on the part of the
driver, and it is no longer possible to activate the
automatic brake device. Furthermore, in the event of a
fault it is not possible to deactivate an already
activated brake device, because as the criterion for
35 deactivation the measuring signals of the sensors must
fall below reference values, but with defective sensors

- 2 -

such measuring signals cannot be generated correctly, if at all.

The problem addressed by the invention is to improve the
5 operating reliability of an automatic brake system.

According to the invention this problem is solved by the features of Claim 1.

10 According to the innovation at least two sensors are provided, the measuring signals from each of the sensors needing to lie within defined activation value ranges for actuation of the brake servo assistance unit to occur; otherwise automatic activation of the brake servo
15 assistance unit is not permitted. This permits a more precise definition of situations in which automatic braking is to be initiated. The system is designed with redundancy, because the activation conditions can be defined in such a way that the signals of one sensor for
20 the activation of the brake system lie in a higher value range, whereas the signals of the second sensor lie in a lower value range.

In a preferred embodiment a temporary, preventative
25 activation can be performed for a limited period of time should the higher reference value of one sensor be exceeded, whilst the lower reference value of the second sensor has not yet been attained. In this situation the conditions for unrestricted activation are not yet met,
30 but activation is nonetheless undertaken for the limited period of time and is advantageously maintained provided that the reduced reference value of the second sensor is exceeded during the period of activation. If the conditions for permanent activation are not fulfilled
35 during the defined period, a deactivation control signal is automatically generated.

This procedure affords the advantage that additional brake force is made available within a shorter response

- 3 -

time. Furthermore, the reactive effect on the driver is reduced, since owing to the limited period of time the braking action only takes partial effect. This avoids causing irritation to the driver.

5

The activation control signal is suitably generated should a gradient be calculated from successive measuring signals of each of the two sensors and the gradients for each of the two sensors exceed a reference value. As an
10 alternative activation criterion, however, it is also possible to take account of the gradient for one sensor and the absolute value for the second sensor. It is furthermore possible to utilize the absolute values from both sensors in order to assess whether activation is to
15 be undertaken.

For deactivation of the brake servo assistance unit it is duly sufficient for the measuring signal from just one sensor to fall below a reference value. Adopting this
20 approach ensures that even in the event of one sensor failing, the automatic generation of brake force is deactivated again provided that the measuring signal from at least one intact sensor delivers a measuring signal that lies within the deactivation value range. This
25 makes it possible to avoid operating situations in which the brake system erroneously delivers brake force even though a situation that justifies the provision of additional brake force no longer exists; the brake system is of redundant design with regard to deactivation and
30 operating safety is improved.

The values for the activation range and the deactivation range may differ, for example, activation occurring at higher values, or in the event of higher gradients
35 derived from the absolute measuring signals, than deactivation. The differing activation and deactivation conditions increase the margin of safety against erroneous, accidental activation of the brake system.

- 4 -

In a first advantageous embodiment, two pressure sensors are provided. The use of two sensors of the same type permits an activation of the brake servo assistance unit for differing pressure values or pressure gradients of the pressure sensors, thereby increasing the fail-safety.

It may be appropriate, however, to design at least one sensor as a travel sensor. Where one pressure sensor and one travel sensor are provided, a current speed value is preferably determined from successive measuring signals of the travel sensor, and together with the pressure gradient of the pressure sensor this is used as the basis for the query as to whether the brake system is to be activated. As an alternative condition, however, account may also be taken of the pressure/speed or pressure gradient/travel combination.

In an advantageous development, it is merely sufficient for the measuring signal of the travel sensor to fall below a reference value, in order to trigger the deactivation control signal.

It may be advisable to provide alternative conditions both for the activation and for the deactivation of the brake system. Activation or deactivation then occurs if just one of the formulated conditions is met.

Further advantages and suitable embodiments are set out in the further claims, the description of the figures and the drawing, which represents a circuit diagram of a hydraulic brake system according to the invention.

The brake system 1 of a motor vehicle comprises an actuating unit 2 for activation of the wheel brake by the driver, a hydraulic unit 3 for transmission and modulation of the required brake pressure and wheel brake units 4 on the front left (FL), front right (FR), rear left (RL) and rear right (RR) wheels of the vehicle. The actuating unit 2 comprises a brake pedal 5, a booster 6,

- 5 -

- a master cylinder 7 and a reservoir tank 8; in addition a trip switch 9 and a travel sensor 10 are assigned to the actuating unit 2. The hydraulic unit 3 comprises two brake circuits 11a, 11b, which are of inverse design construction. The first brake circuit 11a supplies brake pressure to the RL and FR wheel brake units, the second brake circuit 11b is assigned to FL and RR wheel brake units.
- 10 A brake light switch may also be used in place of the trip switch 9.

- When the brake pedal 5 is actuated, the pedal force applied by the driver is boosted by the booster 6, the force generated by the booster 6 being converted in the master cylinder 7, which is fed with hydraulic medium from the reservoir tank 8, into hydraulic brake pressure, which is delivered to the two brake circuits 11a, 11b of the hydraulic unit 3.

- 20 The following description of the hydraulic unit 3 relates only to the first brake circuit 11a, the second brake circuit 11b in the exemplary embodiment shown being of similar construction to the first brake circuit 11a. All components of the hydraulic unit 3 can be adjusted by means of signals from a control unit (not shown).

- The brake pressure generated in the master cylinder 7 is delivered by way of a hydraulic line 12 to the RL and FR wheel brake units of the first brake circuit 11a. The hydraulic line 12 comprises three sections 12a, b, c, a first section 12a branching off from the master cylinder 7 dividing into two further sections 12b, c, which are each

- 6 -

assigned to a wheel brake unit, FR and RL respectively. A servo valve 13a, b, c is arranged in each section 12a, b, c of the hydraulic line 12 and a non-return valve is assigned to each servo valve 13a, b, c, the non-return
5 valve assigned to the first servo valve 13a in the common line section 12a opening in the direction of the wheel brake units, whereas the non-return valves assigned to the other servo valves 13b, c open in the direction of the actuating unit 2. The common line section 12a is
10 connected to a compensating accumulator 21 upstream of the servo valve 13a.

When the driver operates the brake pedal 2, thereby generating a brake pressure, control signals from the
15 control unit move the servo valves 13a, b, c into the opening position, so that the brake pressure from the actuating unit 2 can be delivered to the wheel brake units 4 in order to generate a wheel brake force.

20 The return flow of hydraulic medium is by way of a return line 14, which comprises two line sections 14b, c, which branch off from the feed line sections 12b, c, and a common line section 14a, into which the sections 14b, c open and which in turn opens into the upper section 12a
25 of the hydraulic line 12. A servo valve 15a, b, c is arranged in each section 14a, b, c of the return line 14, an intermediate accumulator and a non-return valve opening in the direction of the return flow being situated in the upper line section 14a between the union
30 of the lower line sections 14b, c and the upper servo valve 15a. The servo valves 15a, b, c may be opened by the control unit for the return flow of hydraulic medium.

In the brake circuit 11a of the hydraulic unit 3 an
35 automatic brake servo assistance unit 16 is furthermore provided, which comprises a hydraulic pump 17, a hydraulic motor 18 and an intermediate accumulator 19 in a line 20, which branches off from the section 14a of the return line 14 and which opens into the common line

- 7 -

- section 12a of the hydraulic line 12 downstream of the servo valve 13a. On actuation of the hydraulic motor 18 and the hydraulic pump 17 respectively, additional brake pressure is generated, which is fed into the common line
- 5 section 12a and delivered to the wheel brake units 4, thereby generating a boosted brake force. The actuation of hydraulic motor 18 and hydraulic pump 17 - both the activation and the deactivation, is triggered by control signals from the control unit as a function of input
- 10 signals, which are generated as measuring signals by the sensors 9, 10 in the actuating unit 2 and, where applicable, by other sensors 22, 23 in the hydraulic unit 3.
- 15 The sensor 9 in the actuating unit 2 is designed as a trip switch, which is installed in the booster 6 and has the function of deactivating the automatic brake servo assistance unit 16 as soon as the brake pedal 5, starting from an actuation position, covers a release travel
- 20 towards the initial home position. In this event, the driver withdraws the pedal force, from which it can be inferred that no additional brake servo assistance is required, whereupon the servo assistance unit is deactivated.
- 25 The further sensor 10 in the actuating unit 2 is designed as a travel sensor, which senses either the control movement of the brake pedal or the control movement of the cylinder in the master cylinder 7 corresponding to
- 30 the control movement of the brake pedal. The sensor 22 in the hydraulic unit 3 is designed as a pressure sensor, which is arranged in the common line section 12a and measures the pressure in the hydraulic line 12.
- 35 The brake servo assistance unit 16 is activated in the event of at least one of the following criteria being fulfilled:
- The pressure gradient in the hydraulic line 12 is calculated from successive measuring signals of the

- 8 -

- pressure sensor 22 in the control unit. The speed with which the brake pedal 5 or the cylinder of the master cylinder 7 is moved is correspondingly calculated from successive measuring signals of the travel sensor 10.
- 5 Should both the pressure gradient and the speed exceed a reference value assigned to each of them respectively, an activation control signal is generated for activation of the brake servo assistance unit 16.
- The pressure value determined in the pressure sensor 22 and the speed value derived from the measuring signals of the travel sensor 10 exceed a reference value assigned to each of them respectively.
 - The pressure gradient derived from the measuring signals of the pressure sensor 22 and the travel determined in the travel sensor exceed a reference value assigned to each of them respectively.
 - The measuring signals from the pressure sensor 22 and the measuring signals from the pressure sensor 23 exceed a reference value in each case. Pressure values and/or pressure gradients may be used as measuring signals. Instead of an arrangement of the pressure sensors spread over two brake circuits, it may also be appropriate to arrange both pressure sensors in one brake circuit.

25 The measuring signals from the sensors must in each case exceed an assigned reference value for an activation control signal to be generated. The reference values may assume different values, especially where two sensors of the same type are provided, the lower value being obtained through multiplying the higher value by a reduction factor, which suitably lies between 0.5 and 1.

30 If need be, a two-stage activation is performed. Once the higher reference value of a sensor is exceeded, but the lower reference value of the second sensor has not yet been attained, a temporary activation can occur for a limited period, which is cancelled again, provided that the lower reference value of the second sensor is not

- 9 -

exceeded during the set period of time. The period of time according to which the temporary activation is proportionately calculated is advantageously between one and ten working cycles of the brake system.

5 Should a higher reference value and at least one lower reference value be exceeded simultaneously in both sensors, activation occurs with no time limit. In this case, deactivation occurs only when the deactivation
10 conditions are fulfilled.

Where appropriate, a time window is allowed, within which the measuring signals or the values derived from the measuring signals from travel sensor 10 and pressure
15 sensor 22 must exceed the corresponding reference value.

The brake servo assistance unit 16 is deactivated by way of the trip switch 9 should the force fall below a force reference value. The trip switch switches as a function
20 of the pedal force acting on the brake pedal.

It may also be expedient, however, to initiate the deactivation should the measuring signal from the travel sensor 10 fall below a reference value, which may differ
25 from the corresponding reference value for activation and may in particular assume a higher absolute value, in order to achieve a relatively rapid deactivation of the servo assistance unit. In addition, further deactivation criteria may be formulated, which are dependent on the
30 pressure value, the pressure gradient or on the speed of the brake pedal control movement. If the deactivation criteria are formulated as a function of the sensor values of the travel sensor 10 or the pressure sensor 22, the trip switch 9 may also be dispensed with.

35 Taking account of two different measuring principles by using a pressure sensor and a travel sensor has the advantage that the failure probability of the brake servo

- 10 -

assistance unit 16 is reduced, because the different types of sensors react to a fault in different ways.

In the second brake circuit 11b a further pressure sensor 23 is provided, which measures the pressure in the second hydraulic line supplying the brake circuit 11b. Doubling the number of pressure sensors in different brake circuits means that the brake system can be designed with redundancy and also formulated with limiting conditions.

Consideration is given to activation of the brake servo assistance unit in particular where the pressure gradients of both pressure sensors 22, 23 exceed a reference value, it being possible to set the reference values at different levels. In an alternative embodiment, activation occurs if the gradient of one pressure sensor and the pressure value of the second pressure sensor each exceed a reference value. In both cases it is possible to set a time window, during which the measuring signals must meet the specified conditions.

Deactivation advantageously occurs should one of the two pressure signals fall below a further reference value - the deactivation threshold.

The two pressure sensors are appropriately arranged in different brake circuits. It may also be appropriate, where necessary, however, to provide two sensors in one brake circuit.

In preferred embodiments, just two pressure sensors, or just one pressure sensor and one travel sensor, or just one pressure sensor, one travel sensor and one trip switch are used throughout the entire brake system. A force sensor or force sensors may also be used as equivalents to the pressure sensor or pressure sensors.

Use is feasible both in open hydraulic circuits and in closed hydraulic circuits of the brake system. The brake

- 11 -

system according to the invention may be designed both with diagonally split brake circuits and with front axle/rear axle split brake circuits.

Patent Claims

1. Brake system for a vehicle, having a brake servo
5 assistance unit (16) for the automatic generation of
brake force and at least one sensor (10, 22, 23) for
the generation of a measuring signal, which
represents an activity on the part of the driver and
can be fed to a brake pressure control unit, it
10 being possible to generate an activation control
signal for the actuation of the brake servo
assistance unit (16) should the measuring signal lie
within an activation value range,
characterized in that
15 at least two sensors (10, 22, 23) are provided for
the measurement of an activity on the part of the
driver and an activation control signal can be
generated should the measuring signals from the
sensors (10, 22, 23) each exceed a reference value.
20
2. Brake system according to Claim 1,
characterized in that
absolute values and/or gradients can be generated as
measuring signals.
25
3. Brake system according to Claim 1 or 2,
characterized in that
the reference values assigned to the sensors (10,
22, 23) are different.
30
4. Brake system according to Claim 3,
characterized in that
the second reference value can be generated by
multiplying the first reference value by a reduction
35 factor of less than one.

- 13 -

5. Brake system according to one of Claims 1 to 4,
characterized in that
an activation control signal can be generated for a
temporary activation of the brake servo assistance
unit (16) for a limited period, should the higher
reference value from one sensor (10, 22, 23) be
exceeded and the reduced reference value from the
second sensor (10, 22, 23) not yet be attained.
6. Brake system according to Claim 5,
characterized in that
the activation is maintained for a limited, defined
number of working cycles of the control unit and
thereafter a deactivation control signal can be
generated for deactivation of the brake servo
assistance unit (16).
7. Brake system according to Claim 5 or 6,
characterized in that
the activation is maintained, should the measuring
signal from the second sensor (10, 22, 23) exceed
the reduced reference value during the defined
number of working cycles.
8. Brake system according to one of Claims 1 to 7,
characterized in that
a deactivation control signal deactivating the brake
servo assistance unit (16) can be generated, should
the measuring signal from at least one sensor (10,
22, 23) fall below a reference value.
9. Brake system according to one of Claims 1 to 8,
characterized in that
at least two pressure sensors (22, 23) are provided
for measuring the activity on the part of the
driver.
10. Brake system according to Claim 9,
characterized in that

- 14 -

the pressure sensors (22, 23) are arranged in a common brake circuit.

11. Brake system according to Claim 9,
5 characterized in that
the pressure sensors (22, 23) are arranged in
different brake circuits.
12. Brake system according to one of Claims 1 to 11,
10 characterized in that
at least one travel sensor (10) is provided for
measuring an activity on the part of the driver.
13. Brake system according to one of Claims 1 to 12,
15 characterized in that
at least one travel sensor (10) and at least one
pressure sensor (22, 23) are provided for measuring
an activity on the part of the driver.
- 20 14. Brake system according to Claim 13,
characterized in that
an activation control signal can be generated,
should the pressure gradient of one pressure sensor
(22, 23) and the speed value calculated from
25 successive measuring signals of the travel sensor
(10) each exceed a reference value.
15. Brake system according to Claim 13 or 14,
characterized in that
30 an activation control signal can be generated,
should the pressure value of the pressure sensor
(22, 23) and the speed value of the travel sensor
(10) each exceed a reference value.
- 35 16. Brake system according to one of Claims 13 to 15,
characterized in that
an activation control signal can be generated,
should the pressure gradient of the pressure sensor

- 15 -

(22, 23) and the travel of the travel sensor (10) each exceed a reference value.

17. Brake system according to one of Claims 13 to 16,
5 characterized in that
a deactivation control signal can be generated
should the measuring signal from the travel sensor
(10) fall below a reference value.
- 10 18. Brake system according to one of Claims 1 to 17,
characterized in that
a trip switch (9) is provided for deactivation of
the brake servo assistance unit, which is installed
in the brake booster (6) of the brake system (1), it
15 being possible to generate a deactivation control
signal, should the measuring signal of the trip
switch (9) fall below a reference value.
19. Brake system according to one of Claims 1 to 18,
20 characterized in that
the measuring signals from the sensors (10, 22, 23)
for generating an activation control signal must
occur within a defined time window.

Abstract

A brake system for a vehicle is equipped with a brake servo assistance unit for the automatic generation of brake force and with at least one sensor for the generation of a measuring signal, which represents an activity on the part of the driver and can be fed to a brake pressure control unit, it being possible to generate an activation control signal for the actuation of the brake servo assistance unit should the measuring signal lie within an activation value range.

In order to improve the operating reliability, at least two sensors are provided for the measurement of an activity on the part of the driver and an activation control signal can be generated should the measuring signals from the sensors each exceed a reference value.

**COMBINED DECLARATION FOR PATENT APPLICATION AND
POWER OF ATTORNEY**
(includes Reference to PCT International Applications)

ATTORNEY'S DOCKET NUMBER
225/50783

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name.

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

BRAKE SYSTEM FOR A VEHICLE

the specification of which (check only one item below):

- ☐ is attached hereto.
- ☐ was filed as United States application
Serial No. _____
on _____
And was amended
on _____ (if applicable).
- ☒ was filed as PCT international application
Number PCT/EP00/04363
on 16 May 2000
and was amended under PCT Article 19
on _____ (if applicable).

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations. §1.56(a).

I hereby claim foreign priority benefits under Title 35, United State Code, §119 of any foreign application(s) for patent or inventor's certificate or of any PCT international application(s) designating at least one country other than the United States of America listed below and have also identified below any foreign application(s) for patent or inventor's certificate or any PCT international application(s) designating at least one country other than the United States of America filed by me on the same subject matter having a filing date before that of the application(s) of which priority is claimed:

PRIOR FOREIGN/PCT APPLICATION(S) AND ANY PRIORITY CLAIMS UNDER 35 U.S.C. 119:
